Class 17: Investigating Pertussis

AUTHOR Hyeseung (Frankie) Son

Investigating Pertussis Cases by Year

Pertussis, or whooping cough, is a highly contagious lung infection caused by a bacteria B. pertussis.

The CDC tracks reported cases in the U.C since the 1920s.

Q1. With the help of the R "addin" package datapasta assign the CDC pertussis case number data to a data frame called cdc and use ggplot to make a plot of cases numbers over time.

```
cdc <- data.frame(</pre>
                                    Year = c(1922L, 1923L, 1924L, 1925L,
                                              1926L, 1927L, 1928L, 1929L, 1930L, 1931L,
                                              1932L,1933L,1934L,1935L,1936L,
                                              1937L,1938L,1939L,1940L,1941L,1942L,
                                              1943L, 1944L, 1945L, 1946L, 1947L,
                                              1948L,1949L,1950L,1951L,1952L,
                                              1953L,1954L,1955L,1956L,1957L,1958L,
                                              1959L, 1960L, 1961L, 1962L, 1963L,
                                              1964L, 1965L, 1966L, 1967L, 1968L, 1969L,
                                              1970L,1971L,1972L,1973L,1974L,
                                              1975L,1976L,1977L,1978L,1979L,1980L,
                                              1981L,1982L,1983L,1984L,1985L,
                                              1986L, 1987L, 1988L, 1989L, 1990L,
                                              1991L,1992L,1993L,1994L,1995L,1996L,
                                              1997L,1998L,1999L,2000L,2001L,
                                              2002L, 2003L, 2004L, 2005L, 2006L, 2007L,
                                              2008L, 2009L, 2010L, 2011L, 2012L,
                                              2013L, 2014L, 2015L, 2016L, 2017L, 2018L,
                                              2019L, 2020L, 2021L),
         Cases = c(107473, 164191, 165418, 152003,
                                              202210, 181411, 161799, 197371,
                                              166914, 172559, 215343, 179135, 265269,
                                              180518, 147237, 214652, 227319, 103188,
                                              183866, 222202, 191383, 191890, 109873,
                                              133792,109860,156517,74715,69479,
                                              120718,68687,45030,37129,60886,
                                              62786,31732,28295,32148,40005,
                                              14809, 11468, 17749, 17135, 13005, 6799,
                                              7717,9718,4810,3285,4249,3036,
                                              3287, 1759, 2402, 1738, 1010, 2177, 2063,
                                              1623, 1730, 1248, 1895, 2463, 2276,
                                              3589,4195,2823,3450,4157,4570,
```

localhost:5131 1/16

```
2719,4083,6586,4617,5137,7796,6564,
7405,7298,7867,7580,9771,11647,
25827,25616,15632,10454,13278,
16858,27550,18719,48277,28639,32971,
20762,17972,18975,15609,18617,6124,2116)
```

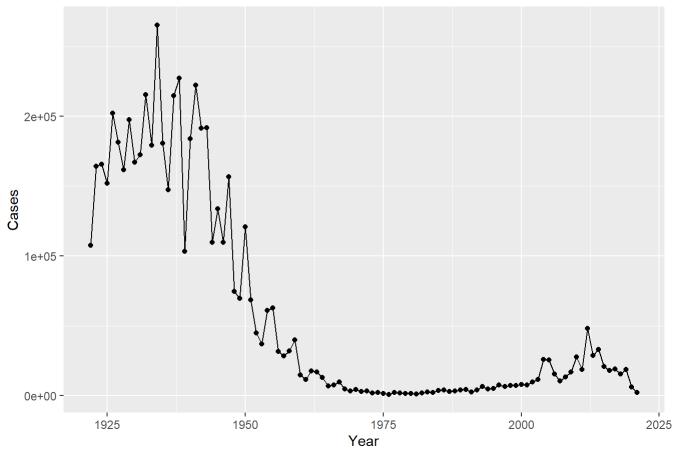

We can now plot the number of reported pertussis cases per year in the U.S.

```
library(ggplot2)
```

Warning: package 'ggplot2' was built under R version 4.2.3

```
ggplot(cdc) +
aes(x = Year, y = Cases ) +
ggtitle("CDC Pertussis Cases by Year (1922-2021)") +
geom_point() +
geom_line()
```

CDC Pertussis Cases by Year (1922-2021)

The first big whole-cell pertussis vaccine program started in 1942.

Examining Two Vaccines

localhost:5131 2/16

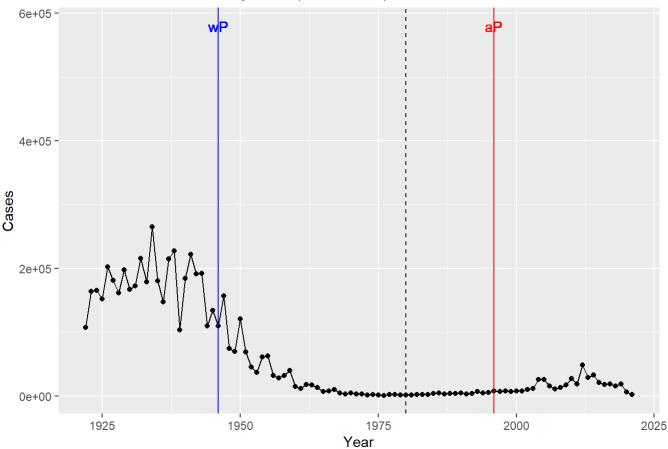

Q2. Using the ggplot geom_vline() function add lines to your previous plot for the 1946 introduction of the wP vaccine and the 1996 switch to aP vaccine (see example in the hint below). What do you notice?

The 1948 introduction of the wP vaccine leads to a significant decrease in cases for a couple decades. There is another increase in pertussis cases after introduction of the aP vaccine.

```
library(ggplot2)

ggplot(cdc) +
    aes(x = Year, y = Cases ) +
    ggtitle("CDC Pertussis Cases by Year (1922-2021)") +
    geom_point() +
    geom_line() +
    geom_vline(xintercept = 1946, color = "blue") +
    geom_vline(xintercept = 1980, color = "gray3", linetype = 2) +
    geom_vline(xintercept = 1996, color = "red" ) +
    geom_text(data = cdc, aes(x = 1946, y = 580000, label = "wP"), color = "blue") +
    geom_text(data = cdc, aes(x = 1996, y = 580000, label = "aP"), color = "red")
```

CDC Pertussis Cases by Year (1922-2021)

Q3. Describe what happened after the introduction of the aP vaccine? Do you have a possible explanation for the observed trend?

localhost:5131 3/16

The bacteria may have gone through evolution by uptake of foreign DNA and developed a resistance to the vaccine, waning vaccine efficacy, which explains the increase in reported cases.

Something big is happening with pertussis cases and big outbreaks are once again a major public health concern!

Exploring CMI-PB data

Enter the CMI-PB Project, which is studying this problem on large scale. Let's see what data they have.

Their data is available in JSON format ("key:value" pair style). We will use "jsonlite" package to read their data.

```
library(jsonlite)
subject <- read_json("https://www.cmi-pb.org/api/subject", simplifyVector = TRUE)
head(subject)</pre>
```

```
subject_id infancy_vac biological_sex
                                                       ethnicity race
                                  Female Not Hispanic or Latino White
1
           1
                      wP
2
           2
                      wP
                                  Female Not Hispanic or Latino White
3
           3
                                  Female
                      wP
                                                         Unknown White
4
           4
                      wP

```

Q4. How may aP and wP infancy vaccinated subjects are in the dataset?

```
table(subject$infancy_vac)
```

```
aP wP
47 49
```

Q5. How many Male and Female subjects/patients are in the dataset?

```
table(subject$biological_sex)
```

localhost:5131 4/16

```
Female Male 66 30
```

Q6. What is the breakdown of race and biological sex (e.g. number of Asian females, White males etc...)?

```
table(subject$race, subject$biological_sex)
```

	Female	Male
American Indian/Alaska Native	0	1
Asian	18	9
Black or African American	2	0
More Than One Race	8	2
Native Hawaiian or Other Pacific Islander	1	1
Unknown or Not Reported	10	4
White	27	13

Q7. Using this approach determine (i) the average age of wP individuals, (ii) the average age of aP individuals; and (iii) are they significantly different?

```
library(lubridate)
library(dplyr)

subject$age <- today() - ymd(subject$year_of_birth)

ap <- subject %>% filter(infancy_vac == "aP")
round( summary( time_length( ap$age, "years" ) ) )
```

```
Min. 1st Qu. Median Mean 3rd Qu. Max. 23 25 26 26 26 27
```

```
wp <- subject %>% filter(infancy_vac == "wP")
round( summary( time_length( wp$age, "years" ) ) )
```

```
Min. 1st Qu. Median Mean 3rd Qu. Max. 28 32 35 37 40 55
```

Q8. Determine the age of all individuals at time of boost?

```
int <- ymd(subject$date_of_boost) - ymd(subject$year_of_birth)

age_at_boost <- time_length(int, "year")
head(age_at_boost)</pre>
```

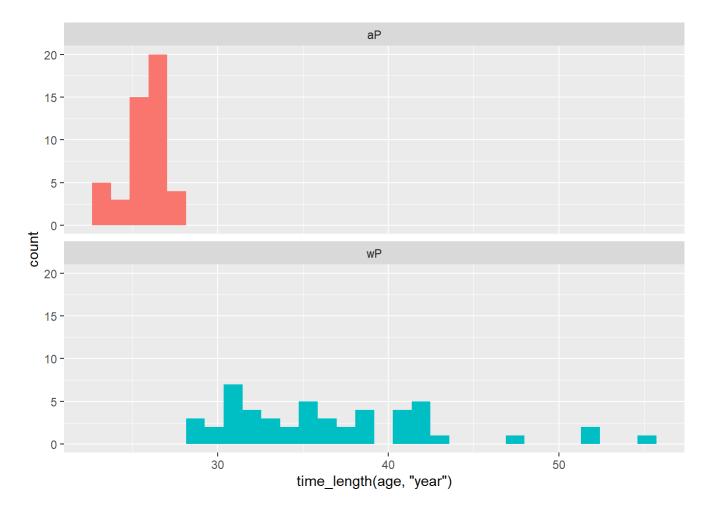

localhost:5131 5/16

[1] 30.69678 51.07461 33.77413 28.65982 25.65914 28.77481

Q9. With the help of a faceted boxplot (see below), do you think these two groups are significantly different?

```
ggplot(subject) +
aes(time_length(age, "year"),
    fill=as.factor(infancy_vac)) +
geom_histogram(show.legend=FALSE) +
facet_wrap(vars(infancy_vac), nrow=2)
```

`stat_bin()` using `bins = 30`. Pick better value with `binwidth`.

Now let's read some database tables from CMI-PB:

```
specimen <- read_json("https://www.cmi-pb.org/api/specimen", simplifyVector = TRUE)
head(specimen)</pre>
```

```
specimen_id subject_id actual_day_relative_to_boost

```

I want to "join" (a.k.a. "merge"/link/etc.) the subject and specimen tables together. I wil use the **dplyr** package.

```
# library(dplyr)

meta <- inner_join(x = subject, y = specimen)
head(meta)</pre>
```

```
subject_id infancy_vac biological_sex

```

Now I can join this data with the "meta" data we created.

Q10. Now using the same procedure join meta with titer data so we can further analyze this data in terms of time of visit aP/wP, male/female etc.

```
abdata <- inner_join(x = meta, y = ab)
dim(abdata)</pre>
```

[1] 32675 21

Q11. How many specimens (i.e. entries in abdata) do we have for each isotype?

```
table(abdata$isotype)
```

localhost:5131 8/16

```
IgE IgG IgG1 IgG2 IgG3 IgG4
6698 1413 6141 6141 6141 6141
```

Q12. What do you notice about the number of visit 8 specimens compared to other visits?

```
table(abdata$visit)
```

```
1 2 3 4 5 6 7 8
5795 4640 4640 4640 4640 4320 3920 80
```

There are way less specimens for visit 8 because this project is still ongoing and we have not got that data for all individuals yet.

Examine IgG1 Ab Titer levels

subject id infancy vac biological sex

We will use the filter() function from dplyr to focus on just IgG1 isotype and visits 1 to 7. Exclude visit 8 because there isn't much data reported.

```
ig1 <- filter(abdata, isotype == "IgG1", visit!=8)
head(ig1)</pre>
```

ethnicity race

```

Q13. Complete the following code to make a summary boxplot of Ab titer levels for all antigens:

Here's a boxplot of antigen levels over time.

```
ggplot(ig1) +
  aes(MFI, antigen) +
  geom_boxplot()
```

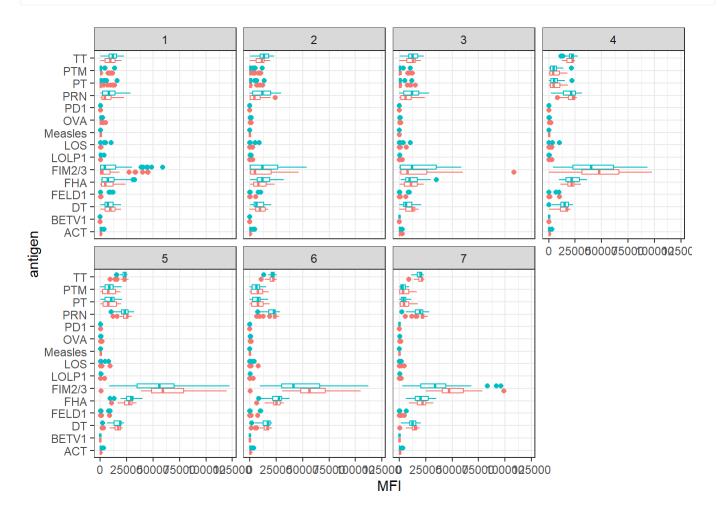

And let's facet this by visit:

```
ggplot(ig1) +
aes(MFI, antigen, col=infancy_vac) +
geom_boxplot(show.legend = FALSE) +
```

localhost:5131 10/16

```
facet_wrap(vars(visit), nrow=2) +
theme_bw()
```

Q14. What antigens show differences in the level of IgG1 antibody titers recognizing them over time? Why these and not others?

Clearly FIM2/3 changes over time. This is "fimbrial protein" that makes the bacterial pilus involved in cell adhesion. This likely is an identifiable tag by antibodies and causes a immune response compared to others.

PT - Pertussis Toxin, found in the extracellular region of the bacteria, and is recognized by antibodies to cause a immune response.

FHAB - "Filamentous hemagglutin" is secreted to the cell surface is responsible for the bacteria's metabolic activities. It is likely another identifiable cell-surface tag.

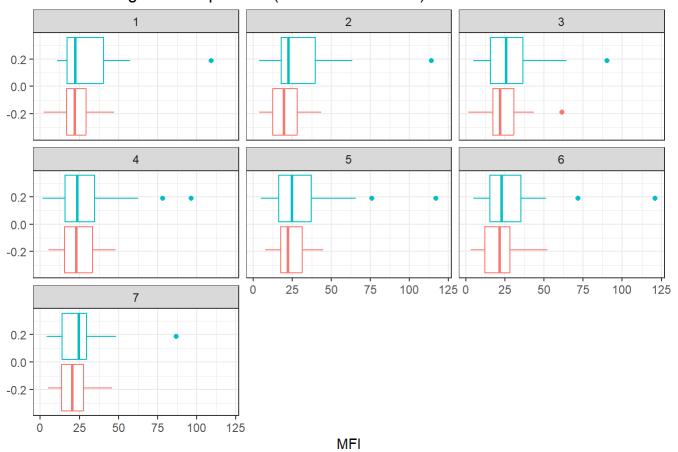

Q15. Filter to pull out only two specific antigens for analysis and create a boxplot for each. You can chose any you like. Below I picked a "control" antigen ("Measles", that is not in our vaccines) and a clear antigen of interest ("FIM2/3", extra-cellular fimbriae proteins from B. pertussis that participate in substrate attachment).

Filter for Measles:

localhost:5131 11/16

```
filter(ig1, antigen=="Measles") %>%
    ggplot() +
    aes(MFI, col=infancy_vac) +
    geom_boxplot(show.legend = FALSE) +
    facet_wrap(vars(visit)) +
    theme_bw() +
    ggtitle("Measles antigen levels per visit (wP = teal/aP = red)")
```

Measles antigen levels per visit (wP = teal/aP = red)

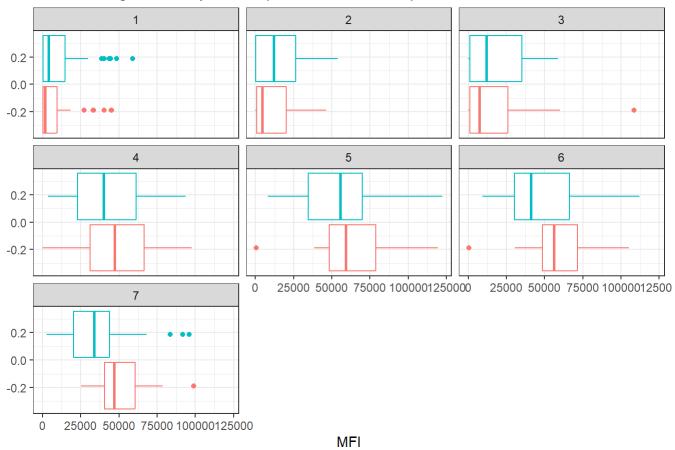

Filter for FIM2/3:

```
filter(ig1, antigen=="FIM2/3") %>%
    ggplot() +
    aes(MFI, col=infancy_vac) +
    geom_boxplot(show.legend = FALSE) +
    facet_wrap(vars(visit)) +
    theme_bw() +
    ggtitle("FIM2/3 antigen levels per visit (wP = teal/aP = red)")
```

localhost:5131 12/16

FIM2/3 antigen levels per visit (wP = teal/aP = red)

Q16. What do you notice about these two antigens time course and the FIM2/3 data in particular?

FIM2/3 levels clearly rise over time and far exceed those of Measles. They also appear to peak at visit 5 and then decline. This trend appears similar for for wP and aP subjects.

Q17. Do you see any clear difference in aP vs. wP responses?

It's hard to tell the clear differences between these responses as it canbe subject to anlaysis and these datasets can also change unknowingly over time.

Obtaining CMI-PB RNASeq data

RNA-Seq data the API query mechanism quickly hits the web browser interface limit for file size. We will present alternative download mechanisms for larger CMI-PB datasets in the next section. However, we can still do "targeted" RNA-Seq querys via the web accessible API.

```
# For example use the following URL
url <- "https://www.cmi-pb.org/api/v2/rnaseq?versioned_ensembl_gene_id=eq.ENSG00000211896.7"
rna <- read_json(url, simplifyVector = TRUE)</pre>
```

localhost:5131 13/16

The link above is for the key gene involved in expressing any IgG1 antibody, namely the IGHG1 gene. Let's read available RNA-Seq data for this gene into R and investigate the time course of it's gene expression values.

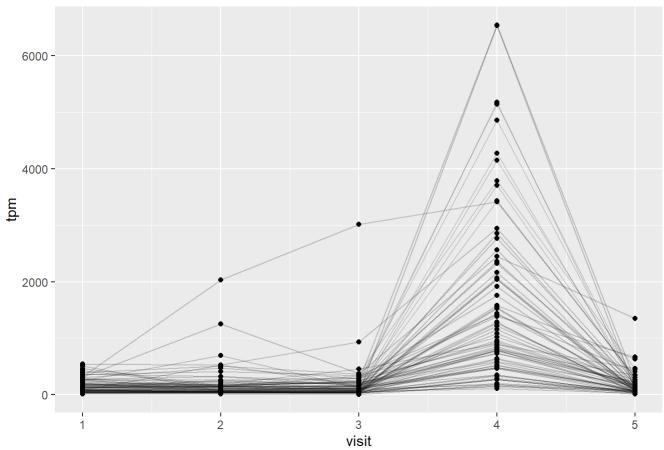

To facilitate further analysis we need to "join" the rna expression data with our metadata meta.

```
#we already joined our meta data previously: meta <- inner_join(specimen, subject)
ssrna <- inner_join(rna, meta)</pre>
```

Q18. Make a plot of the time course of gene expression for IGHG1 gene (i.e. a plot of visit vs. tpm).

```
ggplot(ssrna) +
aes(visit, tpm, group=subject_id) +
geom_point() +
geom_line(alpha=0.2) +
ggtitle("Gene expression for IGHG1 (tmp) vs Time (visits)")
```

Gene expression for IGHG1 (tmp) vs Time (visits)

Q19.: What do you notice about the expression of this gene (i.e. when is it at it's maximum level)?

The expression of this IGHG1 gene is at its maximum level during the 4th visit.

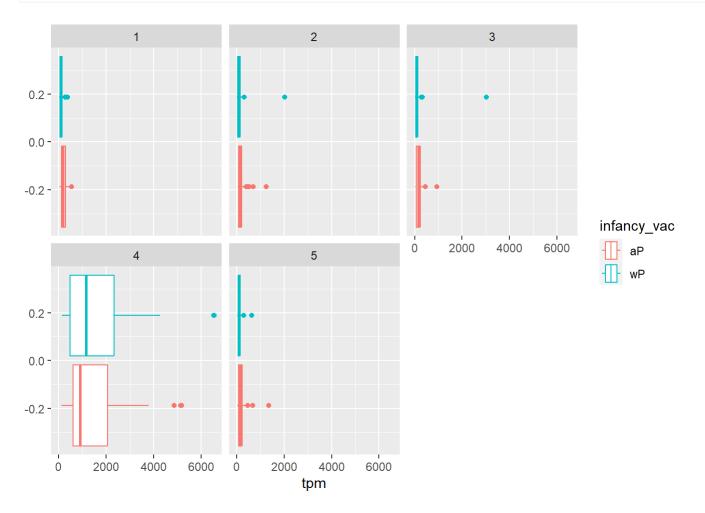

localhost:5131 14/16

Q20. Does this pattern in time match the trend of antibody titer data? If not, why not?

Yes this pattern matches the trend of antibody data because cells make long-lived antibodies.

We can dig deeper and color and/or facet by infancy_vac status:

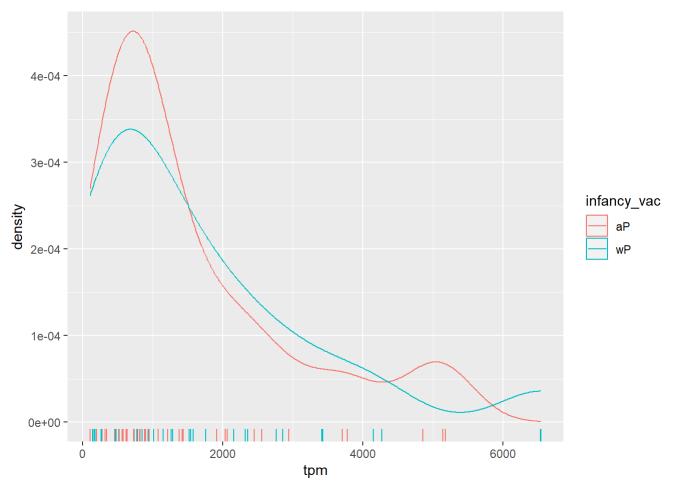

```
ggplot(ssrna) +
  aes(tpm, col=infancy_vac) +
  geom_boxplot() +
  facet_wrap(vars(visit))
```

Even if we focus on a particular visit, there is no obvious wP vs. aP differences.

```
ssrna %>%
filter(visit==4) %>%
ggplot() +
aes(tpm, col=infancy_vac) + geom_density() +
geom_rug()
```
